

Chapter 1: Introduction

This is the introduction. Spaced repetition schedules review of material at increasing intervals to strengthen long-term retention, and this document walks through the theory.

1.1 Background

Retrieval practice — actively recalling an answer rather than re-reading it — produces more durable memories than passive review, a finding replicated across many studies.

Chapter 2: Methods

The FSRS algorithm models memory as two quantities, stability and retrievability, and schedules the next review for whichever moment retrievability crosses a target threshold.

2.1 Data collection

Review logs record every attempt — the card, the grade given, and the interval that had elapsed since the previous review — and this history is what a scheduler is trained on.

Chapter 3: Conclusion

Combining a transparent scheduler with content generated from the reader's own sources is the central bet this whole project makes, and the rest of the document builds on it.
